Data Structure

Now Will See the How Recursive method is Stored in Stack Memory.

```
def recursiveMethod(n):
    if n<1:
        print("n is less than 1")
    else:
        recursiveMethod(n-1)
        print(n)</pre>
```

1st

```
recursiveMethod(3)

recursiveMethod(3)

recursiveMethod(2)

recursiveMethod(1)

recursiveMethod(0)

recursiveMethod(0)

recursiveMethod(0)
```

2nd

Note: See the above image where it states about how Recursion Works.

• one function is there ie; recursiveMethod() user is given input 4 so the flow of the recursive function is the same as in the above image.

Data Structure 1

```
def Loading... (n):
    if n < 1:
        print("n is less than 1")
    else:
        recursive(n-1)
        print(n)
    recursive(4)

n is less than 1
1
2
3
4</pre>
```

3rd

 see the 2nd image based on the LIFO (Stack) as we can see the last method recursiveMethod(0) called. so lastmethod will pop out first. ie; n is less than 1 and so on.

Note: we understood that stack memory is used by the system for managing the recursive calls.

- So every time Recursive method calls itself, the system stores it in the stack for coming back because there are execution (print) statement left after calling itself.
- This means that system somehow remembers the point where it should stops, and call to function with different parameter. based on the condition.

Recursive vs Iterative Solutions

```
def powerOfTwo(n):
    if n == 0:
        return 1
    else:
        power = powerOfTwo(n-1)
        return power * 2
        def powerOfTwoIt(n):
        i = 0
        power = 1
        while i < n:
        power = power * 2
        i = i + 1
        return power</pre>
```

 Here we can see the two functions are given one based on the Recursion, and another based on the iterative traditional method of looping concept.

Data Structure 2

- in the Recursion function, as we can see the above image we have a one condition to stop further execution (Infinite Loop).
- if the condition is not satisfied then it will execute the else block and return the power of 2.
- Conditional statement decides the termination of Recursion.
- Here in Recursive function, infinite Recursion can leads the system crash.
- Recursion repeatedly invokes (triggering) the mechanism consequently (accordingly) as per method calls.
- so conclusion it can be Expensive for both processor time and memory Space.
 as we can discuss in previous section where it recursive function call stored the function in stack memory.

in other side in Iterative solution

- we have created a two variable which is i and power, until i will less than 1 this while loop will execute till that time.
- As per analyzing the two function, Recursion code is easy to write. compare to Iterative one.
- but here variable value of i will decide the termination of execution.
- here in iterative function, infinite iteration consume CPU cycles ie; (CPU usage).
- where in
